

**Central Banks as Architects: The Federal Reserve, the Bank of England,
and the Rise of the Dollar as an International Currency, 1914-1939¹**

Barry Eichengreen and Marc Flandreau

May 2010

In this paper we consider central banks as architects: their role in shaping financial structures and building financial markets, and how their actions can have implications for the place of those markets in the world. The case on which we focus is the making of a market dollar-denominated trade credits (a market in “bankers’ acceptances”) in the early 20th century.

This case speaks to several issues that arise in connection with central banking and monetary policy today. A first issue is international currency competition. It is widely argued that there is only room for one international currency in the global system. The theoretical assertion is that increasing returns to using a national currency in international transactions are strong; network externalities are pronounced. The empirical assertion is that the pound sterling dominated international transactions in the first half of the 20th century, the dollar in its second half. In recent work we have shown that this last assertion is not accurate for foreign-exchange reserves: sterling and the dollar shared the reserve-currency role more or less equally in the 1920s and 1930s.²

From a theoretical point of view, it can be objected that network effects are weaker for international reserves than other international currency functions. But here we show that what was true of international reserves (official use) was also true trade credit (private use). For the bankers’ acceptances used for trade credit, just as for the bonds and deposits used as international reserves, sterling and the dollar shared the market. For those who wish to draw an implication for the 21st century, it is that network effects giving rise to increasing returns have limits.³ There is no reason, therefore, why the dollar and the euro (notwithstanding their respective recent difficulties) cannot both be consequential international currencies.⁴

Related to this is the question of how quickly we should expect China’s currency to gain a consequential international role. As we show, the United States went from a position where the dollar had no place as an international currency and where New York was a negligible source of finance for international trade to one where the dollar was at least sterling’s coequal and New York rivaled London as a source of trade credit in as few as ten years.⁵ This is not to predict that

¹ Prepared for the BIS annual research conference, Lucerne, 24-25 June 2010. Many thanks to Olivier Accominotti, Gopalan Balachandran, Peter Ferderer and John James for their generosity in sharing with us data and insights. They are of course absolved from shortcomings that can only be ours. We are grateful to Hassan Malik, Riad Rezzik, Trevin Stratton, Pierre Turgeon for assisting with the data collection. We also thank the National Science Foundation and Foundation Bank of France for generous funding.

² Something that has obvious implications for thinking about the future. The recent work in question is Eichengreen and Flandreau (2009).

³ Here we echo a point made by Liebowitz and Margolis (1990) in another context.

⁴ Or why other currencies could not eventually join them.

⁵ With some exaggeration, Alexander Noyes, financial editor of the *New York Times*, argued that the replacement of London by New York and of sterling by the dollar occurred “almost immediately” with the outbreak of World War I (Silber 2007, p.168).

the renminbi will necessarily rival the dollar and the euro in 2020. But it does suggest that, if network effects are less powerful than commonly asserted, the renminbi's emergence may be quicker than widely presumed.

Our evidence also highlights the regional dimension of international currency competition.⁶ In the second and third decades of the 20th century, U.S. banks and bankers' acceptances followed U.S. trade, and U.S. trade followed the laws of gravity. Foreign branching by U.S. banks occurred predominantly in places like Latin America where U.S. trade, for reasons of geography, was most extensive. This gives grounds for thinking that the renminbi's role as an invoicing and settlement currency and China's as a source of trade finance will be greatest in Asia, the part of the world with which its trade will grow most rapidly.

Finally, there is concern that central banks' extraordinary actions in 2007-9, taken to provide liquidity to distressed financial markets by purchasing commercial paper, mortgage-backed securities and other financial assets outright, created a reservoir of inflationary pressure that will burst when bank lending picks up. There is concern, in other words, that central banks' market-making and market-supporting actions create a conflict with their price stability mandate. There are fears that central bank action created a new credit bubble destined to burst, and that their interventions merely disguise problems that will become acute once they exit. There is concern about crowding out: central banks' readiness to step in as market makers of last resort may have discouraged other buyers from reentering the market. There is concern that the indiscriminate purchase of securities by central banks will encourage the renewed issuance of financial instruments of dubious quality, setting the stage for another round of financial excesses and problems. We note that the same criticisms were levied against central banks' market-making activities in the 1920s.⁷ While we do not have definitive answers to all these questions, we offer some food for thought.

The remainder of the paper is organized as follows. In Section 1 we provide some historical and institutional background on the case in question. Section 2 then focuses on the transitional period. It shows how dollar acceptances as an instrument for trade finance expanded rapidly in the 1920s from a position of, essentially, nonexistence in 1914. It highlights the actions of the Federal Reserve in promoting the rise of the market. Section 3 looks at the position of the incumbent. We present new evidence showing that sterling shared the status of international currency with the upstart dollar all through the 1920s. Section 4, finally, reports evidence on the determinants of individual American banks' position in the acceptance market. It allows us to assess the relative importance of market forces, meaning trade and the general economic environment, and public policy initiatives, meaning the support from, or "private-public partnership" with, the Federal Reserve, in the growth of the market.

We conclude with a summary and some implications for today.

⁶ See Flandreau and Jobst (2009), who document the influence of trade and geography on currency internationalization before World War I.

⁷ See Rothbard (1963), pp.117-123.

1. Background

Exporters need credit to purchase materials and pay their bills while their merchandise is in transit and payment has not been received. The acceptance was the standard instrument for obtaining such credit prior to 1913. An American exporter would go to his bank with documents indicating that he had shipped the goods and what he would be paid in the future. If his collateral and credit were good, he could get his money immediately rather than having to wait for the goods to arrive in the foreign market and for the buyer's payment to then arrive in the United States.

His bank would finance the operation by drawing on a correspondent (or "acceptor") with which it had made prior arrangement. Upon receipt of the bill, which specified the commodities shipped and the name of the drawer (the U.S. bank), the correspondent whose name was mentioned in the document "accepted" the security. The resulting instruments were thus known as "acceptances." Triply guaranteed (by the goods, by the drawer, and by the acceptor), they could be sold on to other investors. A simple bank-to-customer credit was thereby transformed into a liquid, tradable instrument.

U.S. exports grew faster than those of any other nation in the decades leading up to World War I. By 1912 the United States was the leading trading nation. It is thus striking that virtually no trade credit was provided by U.S. banks or denominated in dollars. Instead, American banks seeking to provide these services to their customers did so through correspondent banks in London. These acceptances were denominated in sterling, since that was the currency with which the London banks, secondary-market investors, and the Bank of England were all accustomed.

The London market had a number of strengths.⁸ It had the great investment banks, known as merchant banks for their origins in helping merchants with the finance of trade in the early 19th century.⁹ Possessing overseas branch networks, they were able to originate a large volume of acceptances. They then turned around and sold this paper on a large secondary market of individual and institutional investors. They could distribute the acceptances to the market either individually or in bulk (in packages known as "parcels") through the agency of bill brokers.¹⁰ In the unusual event that there was no ready purchaser, they could offload them to the Bank of England (at "Bank rate").¹¹ This trio of factors – Britain's early start as a trading nation, resulting in the merchant banks' first-mover advantage; a large and active secondary market; and a market-maker of last resort – made for low costs and strongly increasing returns. They explain why London monopolized the provision of trade credit and why sterling was the dominant international currency. They were why New York and the dollar played no international role.

⁸ As contemporaries such as Jacobs (1910) recognized.

⁹ And also private, joint stock and colonial institutions with international reach.

¹⁰ See King (1936).

¹¹ They could also secure advances from the central bank against the parcels.

There was room for only one international currency. And sterling, with its first-mover advantage, was it.¹²

In fact, the pre-World War I period does not provide a clean test of the strength of increasing returns and the extent of network externalities. An alternative interpretation of why London dominated the market in trade credit to the exclusion of New York is that regulatory prohibitions (and not increasing returns) prevented U.S. banks from entering. Under the National Banking Act, U.S. banks were prohibited from branching abroad.¹³ Federal legislation prevented banks from dealing in trade acceptances.¹⁴ And the U.S. lacked a central bank to backstop the market. Given this, it is hardly surprising that the dollar played no international role.

Two bits of circumstantial evidence are consistent with the alternative view that increasing returns and network effects are limited and that there is room in the market for more than one international currency. First, foreign exchange trading and trade finance go together, and sterling did not monopolize foreign exchange trading.¹⁵ Second, the use of a currency as central bank reserves and in foreign trade and payments go together, smoothing trade and payments being one reason why central banks hold reserves), and sterling by no means

¹² This narrative was prominent in the debates surrounding the creation of the Federal Reserve System. In a pamphlet written for National Monetary Commission, for example, Jacobs (1910, p. 13) deplored a state of affairs in which U.S. bankers were forced to transact via London, observing how this “adds to the importance of London and militates against the development of New York as a financial center.” John J. Arnold, First Vice-President of the First National Bank of Chicago, similarly argued that the “three cornered arrangement” whereby London banks financed American foreign trade could “and should be eliminated” so that a “direct dollar exchange market” be created between the US and South America and the Orient so as to deny London “the undue advantage which this center has had in the past” (Parrini 1968, p. 105). U.S. business and policy leaders supporting the internationalization of New York and the U.S. dollar referred to the amount paid annually to British banks in acceptance fees as the “tribute” (see e.g. Warburg 1910). Of course the metaphor was flawed: British bankers financed American trade more cheaply than New York bankers would have (Phelps 1927, p. 102; Parrini 1968, p. 103). The actual amount involved was a small fraction of U.S. trade or GDP. In 1927, when U.S. banks had secured a large share of the global market for acceptances, the *Acceptance Bulletin* estimated the annual saving to have been a “material” \$5 million. Even this figure is an upper bound, since it does not subtract the resource cost for U.S. banks to supply the acceptances.

¹³ Trust companies could branch abroad, but few did, and those which set up foreign offices did so mainly in order to gather information on foreign bonds, which were attractive assets to add to their portfolios since these matched the maturity of their liabilities to their trustees. Some state-charters also allowed state banks to branch abroad, although few if any ever did. There was one specialized institution, the International Banking Corporation, set up by the Remington Arms Company to assist it in its foreign sales, that operated foreign branches but was prohibited from engaging in domestic banking.

¹⁴ Actually the relevant legislation only lacked provisions explicitly authorizing banks to engage in this business, but the courts, channeling long-standing American suspicion of concentrated financial power, repeatedly ruled against their efforts to do so. While other forms of short term credit emerged, they were less liquid than European style acceptances. One form of short-term negotiable security that came to existence and played some domestic role was the so-called single name “commercial paper.” Commercial paper was issued by industrial and commercial enterprises of substantial standing and traded in organized markets. But while commercial paper paid with “clockwork regularity,” it was relatively illiquid (James 1995, p. 224, drawing on Foulke 1931, pp.80, 84-6).

¹⁵ Flandreau and Jobst (2005) show that bills denominated in sterling, francs and marks had the widest foreign circulation. Those in sterling were traded everywhere, those in francs in 80 per cent of foreign markets, those in German marks in 59 per cent.

monopolized foreign exchange reserves.¹⁶ This is consistent with the presumption that sterling was the leading international currency. But it is inconsistent with the belief that it was the only one.

The evidence in Flandreau and Jobst (2009) also speaks to this question. The authors construct a model of the pre-1914 international monetary system that allows for strategic externalities. Currencies get traded abroad as a function of their value for users. Value is greater when currencies are liquid. This encourages more users to hold liquid currencies and generates positive feedback. Persistence emerges when the feedback loop is sufficiently powerful. Flandreau and Jobst then estimate this model using pre-1914 data and reject the presence of strong lock-in effects. These findings cast doubt on popular notions of network externalities being an insurmountable obstacle to the rise of the dollar.

The 1920s permit a more direct test. The Federal Reserve Act of 1913 created a U.S. central bank authorized to discount and purchase trade acceptances as a mechanism for smoothing interest rates and managing credit conditions. It removed the prohibition on foreign branching and authorized banks to deal in trade acceptances.¹⁷ World War I then disrupted the provision of trade credit by London and the other European financial centers, giving the New York market an opportunity to get up and running.

So one can imagine three hypotheses for what one should expect to see in the 1920s.

- Network effects and increasing returns are sufficiently powerful that London retained its first mover advantage. Lock-in being strong, the equilibrium would not shift even if an alternative was more efficient for the world as a whole.¹⁸
- While network effects and increasing returns are strong, central banks as architects can shift the system from one equilibrium to another. Although New York lacked a secondary market of individual and institutional investors for much of the period, reflecting London's first-mover advantage and the unfamiliarity of U.S. investors with the new instrument, the Fed acted as market maker of last resort, allowing the dollar to supplant sterling as the currency used for trade finance already in the 1920s.¹⁹

¹⁶ According to Lindert (1969), sterling accounted for 51 per cent of identified reserves in 1913, the franc 33 per cent, the mark 16 per cent.

¹⁷ One motive for the act was precisely to create a market in trade acceptances in New York, the belief being that a market in securities backed by receivables would be more stable than one dominated by speculative stock market transactions – this having been a popular explanation for the 1907 financial crisis.

¹⁸ This is essentially the QWERTY story of strong lock-in (David 1985). This presumption is found in some recent historical literature in which it is argued that sterling remained the leading international currency until after World War II as well as in accounts by economists. Modern accounts assert that, once established, London's first-mover advantage was difficult, even impossible to overturn. For example, Roberts and Kynaston (2000, p.192) argue that “the lesson of history is that – once established – leading financial centers retain their primacy until toppled by an external shock.” Michie (2007, p. 78) similarly argues that World War I was a major shock for London's supremacy, but was “insufficient to destroy the strong position it had established in the years before 1914.” Others like Aliber (1968) and, more recently, Chinn and Frankel (2008), have echoed Triffin (1960) in suggesting that dollar only overtook sterling after World War II.

¹⁹ Previous students of strategic externalities (Liebowitz and Margolis 1990) have argued in that the strong lock-in suggested by the QWERTY hypothesis is unlikely. In the conventional tale, large players are able to subsidize

- Increasing returns are not strong enough to give one currency a natural monopoly, and network effects are not sufficiently pervasive for strong lock-in. As a result of both market forces and policy intervention, monopoly gave way to duopoly. Sterling and the dollar could and did share the international currency role in the 1920s.

2. The Rise of New York

The Federal Reserve System played a key role in fostering the international role of the dollar. Here advent means two things. It did so as a carrier of regulatory reform. But it also actively promoted the new market. While the first effect was permanent, the second was more transient, the Fed withdrawing from the market after 1929.

Figure 1 uses interest rates to measure the competitiveness of the London and New York markets. While the cost of acceptance credits had other components (taxes, the bank's commission etc.), the interest rate was the largest part. The interest differential is thus a fair approximation of the relative cost of financing a shipment in the alternative centers and currencies.²⁰ The rate for London is the open market rate – the rate at which acceptances were bought by investors. We compare it to the open market rate on U.S. acceptances when possible. But since U.S. rates for acceptances only become available in January 1917, we also show prime U.S. commercial paper rates (i.e. the rate on prime instruments issued by corporate borrowers of high standing), which begin earlier.²¹

Until World War I, the U.S. commercial paper rate was continually above the open market rate in London, sometimes by as much as 200 basis points. The creation of the Federal Reserve was followed by a sharp reduction in the differential. By 1915 the commercial paper rate was 100 basis points below the London open market rate. In 1917, when dollar acceptance rates become available, they are even lower than commercial paper rates.

adoption of the new standard and, once it is adopted, agents coordinate on it and the subsidy is no longer needed. In our context, these players would be central banks or possibly public-private partnership of banks and policy makers. In this spirit, Ferderer (2003, p.666) argues that “Federal Reserve Banks played a key role by reducing the risk borne by private dealers and propelling the [dollar acceptances] market to a high-liquidity equilibrium.” Silber (2007, p.168) praises the steps taken by Treasury Secretary McAdoo at the onset of World War I to keep the dollar onto gold, persuading markets of its credibility. Had this policy not been implemented, he concludes, “Britain could have easily remained the undisputed, if somewhat battered, champion of international finance until the Second World War. It almost happened.”

²⁰ As argued by Velay (1932, p. 121).

²¹ This is an appropriate comparison, since commercial paper benefited in similar fashion from the new arrangements. The Federal Reserve Act was intended to promote the commercial paper market, and Federal Reserve rediscount rates on commercial paper were close to, if slightly higher than, the rate on acceptances. As recalled by James (1995, p.227), the Federal Reserve Act was defined as “An Act to provide for the Establishment of Federal Reserve Banks ... and to afford means of rediscounting commercial paper.” As for information on dollar acceptances, the editors of the *Acceptance Bulletin* constructed monthly series from material submitted by reporting banks. The resulting series is available January 1917 to April 1936 (the *Bulletin* having been discontinued at that point). From 1917 onward, the *Bulletin* also distinguished acceptances created to finance exports, imports, shipments and goods stored in foreign countries, domestic shipments, domestic warehouse credits and dollar exchange. Federal Reserve reports and bulletins then provide information on acceptances between 1936 and 1939.

Figure 1. London and New York Money Market Rates, 1900-1939

Source: see text.

The period centered on 1915 thus saw a revolution in the relative position of London and New York. These changes may have been due not to the advent of the Fed, of course, but to the dislocations of the war and limited sterling convertibility. However, whereas the latter presumably would have had only transitory effects, the shift in London-New York interest differentials was permanent. While this is consistent with both our second and third hypotheses above, it is inconsistent with the first (emphasizing the overwhelming importance of first-mover advantage).

But this shift from London to New York did not occur immediately on the founding of the Fed. Figure 2 shows that total acceptances outstanding only began to rise in 1915.²² The Guaranty Trust Company credits itself for having been first to begin originating acceptances and allowing foreign correspondents to draw on it and our data supports this, showing 18.2 million USD in acceptances in their December 1914 balance-sheet, at a date when the market was probably not much bigger than that.²³ Over the course of 1915, more bankers then began entering the market. As shown in Figure, 1 this is when the interest differential reversed itself.

²² From Federal Reserve statistics and the *Acceptance Bulletin*.

²³ It complains, however, the acceptances it originated failed to find ready buyers, forcing it to hold its own paper (Guaranty Trust 1919).

The market in acceptances then experienced two boom-and-bust cycles. Toward the end of World War I (coincident with the increase in U.S. trade associated with direct American military involvement), there was a sharp increase in acceptances. The peak reached in 1919-20 was then followed by a sharp decline. The second expansion started in 1922-3 and peaked after the stock market and the real economy in 1929. The subsequent decline in the volume of acceptances persisted through the 1930s.

Figure 2. Total Outstanding Acceptances and Amounts Held by the Federal Reserve Board (Own Account or for Account of Foreign Correspondents), in \$ b.

Source: See text.

Figure 2 highlights the role of the Fed in nurturing the infant industry. The Fed’s *Annual Report* for 1915 points to this year as when the market for acceptances first showed signs of life.²⁴ The Fed also claims a role as midwife: mention is made of how the Federal Reserve Bank of Boston made “every effort to further and develop that business,” buying acceptances from Massachusetts banking institutions engaged in financing “hides and wool from South America and cotton and jute from the orient and other sections of the world” in the early months of 1915, trade that had previously been financed “through credits drawn on European centers.”²⁵

Figure 2 also shows acceptances in the Fed’s custody from 1915 through 1939. It points to periods like 1917 when the central bank was evidently the only purchaser on the secondary

²⁴ See the Federal Reserve Board’s *Annual Report for 1915*.

²⁵ The report also mentions that 7 additional banks in the area had moved into the acceptance business (Federal Reserve System, *Annual Report for 1915*, p. 136).

market.²⁶ On average the Fed was holding between a quarter and two-thirds of outstanding acceptances.²⁷ Suggestively, the withdrawal of the Fed from the market coincides with the decline of the industry in the early 1930s.

Figure 3. Share of the Fed in the Acceptance Market and Relative Interest Rates

Source: Authors' computations from sources in text.

Figure 3 juxtaposes two indicators of official support for the market. The first is the Fed's holdings as a share of outstanding acceptances. The second is the spread between the Federal Reserve and market rates for acceptances. The narrower the spread, the stronger the support (a lower spread suggesting that the Fed was more anxious to step into the market). Except in the wake of the two trade busts (1921 and 1931), the Fed kept its rate close the market rate and purchased a substantial fraction of acceptances outstanding.

3. The Empire Strikes Back

The outbreak of World War I was a challenge for the British monetary authorities. Figure 4 shows the correlation between Bank rate (the Bank of England's rediscount rate) and the open

²⁶ Holdings are measured here as total holdings, i.e. holdings for its own account and for the account of foreign customers, mostly central banks.

²⁷ Again, either on its own account or on that of foreign central banks holding deposits with it.

market discount rate before and after 1914 (analogous to Figure 3 for the United States). The correlation loosens during and after the war, suggesting that the Bank of England, grappling with a weak sterling exchange rate, could not support the market as freely.²⁸

Figure 4. Bank of England Rediscount Rate and Open Market Rate 1900-1939

Source: NBER Historical Macro Database.

But, notwithstanding those other difficulties, determined efforts were made not just to maintain the position of the London acceptance market but to expand its reach.²⁹ The war created an opportunity to address the challenge from German banks and the potential challenge from the United States. Concern was voiced that Britain faced the fate of Holland in the 18th century when it became more trader than exporter.

In 1916, a blueprint for a post-war UK-centered international system was described at the Paris Economic Conference. Market access and shipping privileges would be used to reward allies and punish enemies and neutrals – meaning Germany and the United States, respectively. Reliance on the Empire, together with selective Continental alliances, would provide the critical mass for a London-centered European commercial and financial system.³⁰

International, overseas and merchant banks were encouraged to expand their geographical reach and received active official support. The British authorities seized the London branch of the Anglo-Austrian Bank (a leading Vienna based institution with links to Germany). Once the

²⁸ See Sayers (1967) for a discussion of the conflicts created by the multiplicity of policy objectives during the 1920s and the partial remedies found to deal with it.

²⁹ See Robinson (1923), Baster (1935) and Jones (1995).

³⁰ Parrini argues that US declaration of war and Wilson’s sponsoring of the League of Nation were direct responses to this challenge. They led Britain to revise earlier plans and offer the U.S. “co-chairmanship” of the global trading and financial system (Parrini 1967).

government and its friends in the private sector acquired its records and correspondence, they could see how its affiliated institutions operated in Central Europe. This knowledge “eased the way for private British interests to seize control of the Anglo-Austrian network.”³¹ After the war, such expropriations were justified under Article 248 of the Versailles Treaty permitting the organization, in 1922, under the aegis of the Bank of England of the “new” Anglo-Austrian Bank, which in turn controlled the new Anglo-Czech Bank, formed to take over the branches of the former Anglo-Austrian bank in Czechoslovakia. Similar policies were adopted for Turkey, where German banks had had a prominent role before World War I and which like the Habsburg Empire had been an ally of Germany.

To what extent did these policies extend sterling’s reach? Consider Latin America. Before World War I, the role of the mark in financing Latin trade had expanded on the basis of growing German industrial exports. Integral to this process were German overseas banks: the Banco Aleman Transatlantico, the Deutsch-Sudamerikanische Bank, Brazilianische Bank für Deutschland, and the Bank für Chile un Deutschland, which were active primarily in Argentina, Brazil and Chile.³² Most were controlled by or affiliated with the “great banks” that were the pillars of the German banking system.³³

With the outbreak of the war, Downing Street set to limit Germany’s capacity to trade and the German banks’ ability to extend trade finance. The Latin and London branches of German overseas banks were shut down or expropriated.³⁴ Utilizing information obtained through these expropriations, British merchant and overseas banks moved to fill the vacuum. Table 1 shows data for 1913 and 1921 assembled from the *Bankers’ Almanac*. We compare Germany’s four Latin American banks with three British rival. As can be seen, German overseas banks lost their parent connections in London and were replaced by British merchant banks. The merchant houses that moved, Kleinworts, Shroders, and Seligmans, were well-established London institutions of German origin and with a strong German information base. Where the capital and balance sheets of British and German banks operating in Latin America had been comparable in 1913, British banks were much larger in 1921.³⁵ We take this as indicating that accounts suggesting that the war was good for the U.S. but bad for Britain lack balance. The elimination of German competition could and in some cases did reinforce the position of London.³⁶

Figure 5. Dollar and Sterling Acceptances 1927-1937 (millions of £)

³¹ Parrini (1967), p.129.

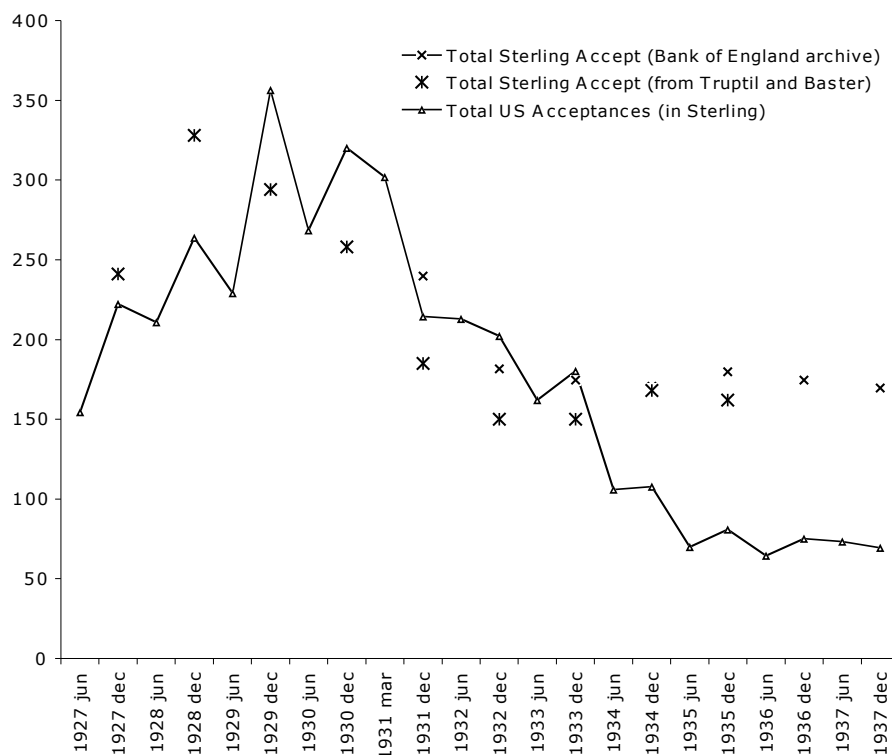

³² See Battilossi (2006) and Briones and Villela (2006).

³³ The Deutsche Bank, the Discontogesellschaft, or the Dresdner Bank. Such arrangements were not specific to Latin America. The Deutsche-Asiatische Bank for instance was active in China.

³⁴ In 1914, the Allies forced the Deutsch-Asiatische Bank Branches in China to shut down. These branches were barely able to resume their operation in 1918. See King (1989) and Horesh (2008).

³⁵ Inflation played a role in the reduction in the capital base but geopolitical dislocations were decisive. Had shareholders of German overseas banks felt that recapitalization would bring revenues they would have supplied the needed resources.

³⁶ We also find the grabbing hand where did not expect it. with the UK and U.S. stripping Germany from its banking system and taking advantage of the war to expand dramatically.

Source: Authors' estimates based on documents described in the text.

What was the net effect on the sterling and dollar acceptance markets? Figure 5 shows the evolution of dollar and sterling acceptances.³⁷ We use here the most comprehensive definition of sterling acceptances, meaning both those drawn abroad and those drawn domestically, and the corresponding U.S. totals.³⁸ The value of dollar and sterling acceptances was quite close in the late 1920s. This figure for private international claims resembles to a striking degree the findings of Eichengreen and Flandreau (2009) for official international reserve holdings.

Again as with official reserves, the dollar's share then shrank in the economic crisis of the 1930s. Where the value of sterling acceptances fell by half between the peak in 1929 and the middle of the 1930s, dollar acceptances in 1935 were barely a seventh what they had been in 1929. Again, this parallels what we found previously for changes in the composition of international reserve holdings between the 1920s and 1930s. In the case of acceptances (as in the

³⁷ There is no British equivalent of the *Acceptance Bulletin* (no central body collected relevant information). The figures we report are for the sub-period 1927-1937. Truutil (1936, p. 159 ff) used material from the Committee on Finance and Industry (1931) together with assumptions about stability of various types of banks' proportions in totals to impute missing information. Baster (1937) then extended Truutil's estimates. We have also drawn on unpublished estimates by the Bank of England. Starting in the 1930s the Bank provided estimates of the volume of acceptances (Bank of England Archive EID4/86). We thank Olivier Accominotti for this material.

³⁸ This seems to be the best way to go: because domestic trade could also be financed by domestic drafts, trying to disentangle domestic and foreign drafts is hopeless. Statisticians of British acceptances typically attempt to identify acceptances from banks' balances-sheets, as the publishers of the *Acceptance Bulletin* did for the United States.

case of reserves), the fact that the U.S. depression was more severe and that U.S. trade contracted more rapidly than British trade is part of the story, but only a part. We return to this.

The picture that emerges from this section is one of competition between two international currencies, not the dominance of one. Reinforcing the point, Figure 6 compares the market-bank spreads for London and New York. After 1922, spreads in the two markets are comparable. Insofar as the spread between official and market rates is indicative of central bank support, Figure 6 is telling us that central banks and currencies competed against with another.

The 1930s then saw both central banks walk away from the market, the Fed even more so than the Bank of England. There is a striking correlation with Figure 5, which shows total U.S. acceptances declining much more dramatically than total British acceptances.

4. Evidence

In this section we look more closely at the growth of the dollar acceptance market in the 1920s. A first interpretation of this phenomenon is as market led. U.S. banks were capable of entering the market; they only had to be freed of regulatory restrictions. A second interpretation is that the transition was government led. It would not have occurred had the Fed not substituted for the missing secondary market.

One can identify two variants of the market-led hypothesis. One emphasizes branching. Overseas branches were needed to gather information on foreign markets of the sort that the London banks had traditionally. They were needed in order to be able to conveniently attract the business of merchants who did not reside in the United States. This is the dominant view in much previous historical research.³⁹

The other variant is that U.S. banks, once liberated from restrictions on dealing in trade credit, could build on their existing connections with importers and exporters. To make acceptances one only needed correspondents abroad, competitive discount rates, reasonable transaction costs making the drawing of drafts on New York attractive, and access to a sufficiently large clientele. It was foreign trade and not foreign branches on which the new acceptance business rested. Previous scholars have paid less attention to this hypothesis, but Figure 6 is at least consistent with it.

Figure 6. U.S. Trade (Imports plus Exports) and Total Acceptances Outstanding

Source: See text.

Table 2 summarizes the extent of branching.⁴⁰ The number of banks that developed networks of foreign branches, either directly or through subsidiaries, was limited. National City

³⁹ See Phelps (1927), Lewis (1938), Parrini (1969), Cleveland and Huertas (1985), Stallings (1987) and more recently, Cattani and Tschoegl (2002).

⁴⁰ On the surface previous estimates differ, although on closer inspection discrepancies can be explained away. This we did by constructing our own estimates from the *Bankers' Almanac*. Phelps provides a table with number branches by bank at some benchmark years (1913, 1920, 1926) and another one with banks by region in 1926

Bank, First National Bank of Boston, Guaranty Trust, and Chase dominate the list. Other institutions boasted “representative offices,” but these representatives (sometimes single individuals) in other countries were not branches proper.

Table 3 shows the value of acceptances originated by bank.⁴¹ While banks with foreign branches usually ranked at the top, it appears that the acceptance market was competitive. The low Herfindhal-Hirschman acceptance market concentration index of 0.47 that we can compute for May 1, 1917 (from data in Kniffin 1920) is consistent with this fact. Using data in the *Acceptance Bulletin* and from bank’s balance sheets, we see that the top four banks accounted for 30 per cent of the market at the end of 1927, a substantial but not overwhelming fraction; to get 85 per cent, one must consider 40 banks.⁴² Given the fact that a fair number of banks with few or no foreign branches appear to have been active in the market, one can question the conventional view that branching was key. The alternative interpretation would be that in order to increase acceptances one only needed good correspondents abroad, competitive discount rates, reasonable transaction costs making the drawing of drafts on New York attractive, and ready access to a sufficiently large clientele.

We now analyze these factors more systematically. Each bank, we assume, originates acceptances in proportion to capital and reserves (to which acceptances were tied through regulation or balance-sheet).⁴³ The bank’s acceptance business was also influenced by the total size of the market (the demand for trade credit), as captured by the value of acceptances or total U.S. trade (imports plus exports). Finally, we ask if branches matter.

Data come from balance sheets for the period 1915-1939 for 20 banks.⁴⁴ In the illustrative example below (Figure 7), acceptances appear both on the asset side (they are claims on customers) and on the liability side (the bank has committed itself to pay the amount at maturity).⁴⁵ Balance sheets were also used to gather figures for other bank attributes (capital, reserves, total assets etc.). U.S. trade is from the NBER database, total acceptances from the *Acceptance Bulletin* and Federal Reserve’s *Banking and Monetary Statistics*. All variables are in logs.

(Phelps (1927), 211& 212). Lewis (1938) expands Phelps’ table for branching to 1919, 1924, 1929, 1933, and 1935. Parrini (1969, p.116) offers a decomposition of branching in 1920 by country and banking “family” (the National City-International Banking Corporation conglomerate vs. the Morgan affiliates. Cleveland and Huertas (1985, pp.324-5 provide a table describing National City Bank/Citigroup per region. Finally Stallings (1987 p.70) tracks U.S. branches in Latin America between 1914 and 1930. *The Bankers Almanac* gives for each city a list of institutions in operation. This being a British source, it may however have undercounted U.S. banks.. Where Phelps and Lewis list 57 National City Company branches in 1920 when Cleveland and Huertas have 81. As shown in the table, Cleveland and Huertas must be considering all the branches of the National City complex.

⁴¹ This is assembled from the *Acceptance Bulletin*’s league tables for the value of acceptances originated.

⁴² *Acceptance Bulletin* (January 1928), pp. 3-4.

⁴³ The Federal Reserve Act authorized national banks to purchase or discount acceptances up to 50 per cent of capital. The ceiling was raised to 100 per cent subsequently.

⁴⁴ They come from the Baker Library at Harvard, Columbia’s Online Digital Collection, the British Library and the Graduate Institute collection of banks balance-sheets. There are, not unexpectedly, missing observations.

⁴⁵ Real- life situations tend to be more complex. Occasionally, acceptances on the liability side are mixed with related securities like credit lines. It was generally possible to get fairly reliable numbers, which were checked against the rankings in *The Acceptance Bulletin*’s league tables.

We use a simple dummy variable for branches. While some banks branched more heavily than others, it is hard to know how to weigh a single branch in Paris against several branches in Cuba. Reassuringly, results were not affected by alternative specifications.⁴⁶

The panel is unbalanced owing to missing observations (some banks were merged, others were closed). We provide two sets of panel estimates, with and without clustered the standard errors. The latter may be probably more appropriate, since we are combining bank-level and macroeconomic variables, where the latter vary by year but not by bank.

Tables 4 and 5 show the results. Bank size, whether measured by total assets or capital, is generally significant and has a positive effect.⁴⁷ The macro variables – total acceptances and total trade – are significant and positive.⁴⁸ Finally branching is in general significant. The existence of branches is associated with a 60 (upper bound estimate) per cent increase in outstanding acceptances.

But magnitudes matter: what do the estimates imply for the role of branching in the growth of the market? Recall that the top four banks controlled about 30 per cent of the total market for acceptances in 1928. Our estimates imply that, had not been for their branches, they would have had only 20 per cent of the market, a noticeable but not ruinous decline. The conclusion, therefore, is that branches helped but were not indispensable to the growth of the

⁴⁶ We abstract from reverse causation. It could be, of course, that branching does not add more acceptances, but that banks that did a number of things had more acceptances and had then to branch in order to meet customers' needs. However, considering this would weaken the case for branches, and given our later finding, this is not essential for us as it would only strengthen our conclusions.

⁴⁷ Introducing capital and total assets together creates a problem of multicollinearity, as one would expect.

⁴⁸ Although, again, multicollinearity is an issue.

acceptance market. Banks that did not go overseas were still able to enter the market, making use of their established connections with U.S. importers and exporters.

Tables 6 and 7 assess the contribution of the Fed. Table 6 considers a narrow definition of Fed's support: total acceptances held on the Fed's own account. This variable tends to be statistically significant at conventional confidence levels even when it is included together with total acceptances outstanding and U.S. trade, with which it is collinear.⁴⁹ The point estimates move around (as a function of which control variables are included), but they uniformly suggest that Fed purchases were as important as the aggregate growth of the market for individual bank behavior. Knowing that it might be possible to lay off acceptances on the Fed caused individual banks to respond roughly twice as fast to market growth as otherwise. This makes sense: acceptances brought revenue while immobilizing close to zero capital. Banks thus were prepared to issue as many as they would be sure to sell. If by contrast there were less buyers and banks faced the risk of having to buy their own paper, the cost of underwriting more acceptances rose, rendering banks more reluctant to originate them.

The narrow definition of support may not be the best one. The Fed also received deposits from foreign central banks (prominently from the Bank of France) which it then parked as acceptances, again in part to foster the growth of the market. While the Fed did not determine the amounts deposited, it certainly decided what it would do with it – that it would recycle them as acceptances as opposed to other forms of deposits. In Table 7 we therefore add these acceptances held by the Fed for the account of others to acceptances purchased for its own account. The official-purchases variable is now even more significant than before, reinforcing the conclusion that they played an important-market making role.

The results from Tables 6 and 7 strongly suggest that, to the extent that the Federal Reserve helped the market through active purchases during the 1920s, it must by definition have penalized it when it withdrew in the 1930s. Evidently, the failure of the Fed to support the market after 1931 was an important factor in its absolute and relative decline.

5. Conclusion

This paper has offered new evidence on the rise of the dollar as an international currency during World War I and the interwar years. As a heuristic we have used the analogy between international currencies and standards in technology. The question is whether the international monetary and financial system of the era was subject to strong lock-in and irreversibility, whether it could in fact be shifted from one equilibrium to another by large shocks and the actions of large players like central banks, or whether there were in fact limits on increasing returns and network externalities, permitting several monetary technologies to coexist.

Much previous literature emphasizes the first hypothesis, and a good deal favors the second. It is argued that sterling remained the dominant current in private as well as official international transactions until after World War II, long since the United States surpassed Britain as the largest economy and leading trading nation. It is said that this lag between shifts in economic and monetary circumstances reflected the strength of increasing returns, network externalities, and London's first-mover advantage. When the shift finally occurred, it reflected

⁴⁹ In this table and the one that follows we continue to cluster the standard errors.

the shock of the war and the support provided by the Fed. To the extent that market forces played a role, they were mediated by the foreign branching of U.S. banks.

In this paper we have challenged this conventional wisdom. We show that the shift occurred already much earlier, during and after World War I. Already in the 1920s the dollar rivaled and, indeed, surpassed sterling as a source of trade credit. This finding parallels what we found previously for the official use of international currencies (that is, for the composition of central bank reserves).

We show next that it was not merely the growth of foreign branches but also the growth of U.S. trade that allowed U.S. banks to enter the market. To build acceptance business, one only needed good correspondents abroad, competitive discount rates, access to a large clientele, and the removal of regulatory restrictions on dealing in this paper.

We show third that not just market forces (the actions of American commercial banks and trust companies) but also public support – the Fed’s role as architect – played a role in the dollar’s rapid overtaking of sterling as the leading international currency. It took time to build the liquid secondary market of private and institutional investors to which the acceptances originated by U.S. banks and trust companies could be resold.⁵⁰ In the meantime, the Fed stepped in as secondary-market-maker of last resort. Our estimates suggest that the U.S. market in trade acceptances grew twice as fast as it would have in the absence of this official support. There is a message here for governments like China’s seeking to promote international use of its currency.⁵¹

We show fourth that when central banks stepped out of the market for acceptances in the 1930s, the market in dollar acceptances collapsed all but completely, whereas the market in sterling acceptances did not. Evidently the task of building a new secondary market of individual and institutional investors, analogous to what London had already done in the 19th century, was more difficult than supposed. Indeed, the Fed’s aggressive intervention as buyer of last resort may have stifled rather than fostering the development of that market.

We show finally that the image of strongly increasing returns and pervasive network externalities leaving room for only one monetary technology is misleading. There were limits to these network effects. There was room for both sterling and the dollar and for both London and New York all through the 1920s. This suggests that there will be room for more than one international currency in the 21st century. It is not a winner-take-all game.

⁵⁰ As explained by the industry’s advocate, the American Acceptance Council, the investor “would have to be educated, first as to the nature of a bankers’ acceptance, second as to its attractiveness as an investment, and third, owing to its quality as a doubly secured risk [that it was guaranteed both by the original issuer and the accepting bank], that it would be offered at a lower rate than he had been accustomed to, when buying the best single name commercial paper.” American Acceptance Council (1931), p.17.

⁵¹ China has already begun moving in this direction by encouraging limited use of the renminbi for trade settlements. It is negotiating arrangements with Brazil whereby the two countries can use their own currency in bilateral transactions. It has allowed select banks to issue renminbi-denominated bonds in Hong Kong and done a sovereign bond issue in renminbi there itself. It has allowed the multilaterals to issue renminbi-denominated securities in Shanghai.

Data Sources for Regression Analysis:

US Banks data:

Extracted from 31st December balance-sheet (or closest available date). Balance-sheets were collected from Baker Library (Harvard), Columbia University Library, British Library (London) and Graduate Institute Library (Geneva). The banks in the sample are as follows (periods for which we have data are indicated).

American Exchange Irving Trust 1927-1928
Bank of New York and Trust Company 1922-1938
Bank of the Manhattan Company 1924-1935 (missing years)
Bankers Trust Company 1915-1935
Central Hanover Bank and Trust Company 1930-1935
Chase Bank 1915-1938 (missing years)
Chemical Bank and Trust Company 1929-1935
Commercial National Bank and Trust Cy of NY 1929-1939
Continental Illinois National Bank and Trust Company 1932-1935
First National Bank of Boston 1915-1935
First National Bank of Chicago 1915-1935
Guaranty Trust 1914-1937
International Accpetance Bank 1929
Irving Bank-Columbia Trust Company 1920-1926
Manufacturers Trust Company 1924-1935
Marine Midland 1929-1935
National City Bank of new york 1915-1935
National Bank of Commerce in New York 1923-1928
Old Colony Trust Company 1919-1929 (missing years)
New York Trust Company 1920-1935
Philadelphia National Bank 1926-1935 (missing years)
Wells Fargo 1921-1935

Heavy Branching dummies:

Dummy equals 1 for Chase, First National Bank of Boston, Guaranty Trust, National City Bank

Total Acceptances Outstanding:

December totals from Acceptances Bulletin and Federal Reserve, as described in Text.

Federal Reserve Holdings of Acceptances (own and foreign accounts).

December observation from Federal Reserve Publications
